

Frontend Developer Technical Test Assessment

Project: Health Insight Dashboard

Overview

Build a modern, responsive web application that helps a user understand their personal health and wellness information.

You will be given a fictional user persona and a set of health-related data.

Your goal is to turn this data into a **clear, useful, and engaging health dashboard**.

There is no predefined design or exact layout to follow. We want to see how you think about the product, what information you prioritize, and how you choose to present it.

1. Health Dashboard

Create a dashboard that helps the user understand their current health status and progress.

You may decide how to organize and visualize the information.

The dashboard could include things such as:

- Health metrics
- Progress over time
- Activity
- Sleep
- Nutrition
- Goals
- Trends
- Recommendations
- Recent activities

Use appropriate visualizations, cards, lists, or other UI patterns where they make sense.

The important question is:

If you were building this product for a real user, what would you show them and why?

2. AI Health Assistant

Add a floating AI assistant in the bottom-right corner of the dashboard.

When opened, the user should be able to ask questions about their health information.

For example:

- "How am I progressing?"
- "What should I focus on?"
- "How has my activity changed?"
- "Give me a summary of my current health."
- "What are some areas I could improve?"

The assistant should use the information available in the dashboard when generating its responses.

You must integrate an **actual LLM API**.

The choice of LLM provider is up to you.

3. LLM & Prompt Design

We want to understand how you approach AI integration, not just whether you can make an API request.

Design your prompts so the model has appropriate context about the user and their data.

Consider:

- How you provide the health data to the model
- How you structure the prompt
- How you maintain conversation context
- How you handle unexpected or invalid responses
- How you prevent the model from inventing information that is not available

You are free to decide how the LLM response should be structured and rendered.

Please briefly explain your approach in the README.

4. Frontend Requirements

Use:

- React
- TypeScript
- Redux Toolkit or another reasonable state-management solution

You may choose your own:

- UI library
- Styling approach
- Charting library
- Project structure
- API architecture

The application should be responsive and handle appropriate loading, error, and empty states.

5. Submission

Submit a GitHub repository containing:

- Source code
- README.md
- Setup instructions
- Environment variable documentation
- Brief explanation of your architecture
- Explanation of your key product decisions
- Explanation of your LLM/prompt approach

Do not commit API keys or other secrets.
